Introduction to Automated Polyhedral Code Optimizations and Tiling

Alain Darte

CNRS, Compsys team
Laboratoire de l’Informatique du Parallélisme
École normale supérieure de Lyon

Spring School on Numerical Simulation and Polyhedral Code Optimizations
Saint Germain au Mont d’Or, May 10, 2016
Outline

1. Generalities
2. Polyhedral compilation
3. Classic loop transformations
4. Systems of uniform recurrence equations
5. Detection of loop parallelism
6. Kernel offloading and loop tiling
7. Inter-tile data reuse and local storage
GENERALITIES
Compiler: generalities
Compiler: generalities

- AoT vs JIT
- Static vs dynamic
- Cross compilation
- Parametric codes
- Worst-case opt. vs average-case opt.
- Language-specific or multi-language
- Intermediate representations (IR)
- Runtime & libraries
Front-end and back-end

Structure of Compiler

Front-end
- Target independent
- Source-to-source
- High-level transf.
- Task & loop par.
- Memory opt.

Back-end
- Target dependent
- Instr-level par. (ILP)
- Pipelining
- AVX, SIMD instr.
- SSA and registers

Moore’s law and Dennard scaling

Moore’s law (1965)
- Number of transistors 2x every 2 years, performance x2 every 18 months.

Dennard scaling (1974)
- Scaling size, voltage, frequency, with constant power density: \( P \sim CV^2f \).
Moore’s law and Dennard scaling

Moore’s law (1965)
Number of transistors 2x every 2 years, performance x2 every 18 months.

Dennard scaling (1974)
Scaling size, voltage, frequency, with constant power density: $P \sim CV^2f$.
If reduction of width gates by factor $\lambda$:
- Reduction by $\lambda$ of capacitance ($C \sim A/\Delta$).
- Reduction by $\lambda$ of voltage, intensity, and delay time ($1/f \sim CV/I$).
- $P' = (C/\lambda).(V^2/\lambda^2).(\lambda f) = P/\lambda^2$ thus power density constant.
- Or can reduce $V$ by less with better $f$, but power increase.

End of Dennard scaling
$\text{frequency max around 2006 (} \sim \text{4 GHz)}$. 
ILP, low-power CPU designs, multicore designs, GPUs.
More burden on the programmers & compilers.

6/98
Moore’s law and Dennard scaling

Moore’s law (1965)
Number of transistors 2x every 2 years, performance x2 every 18 months.

Dennard scaling (1974)
Scaling size, voltage, frequency, with constant power density: \( P \sim CV^2f \).
If reduction of width gates by factor \( \lambda \):

- Reduction by \( \lambda \) of capacitance (\( C \sim A/\Delta \)).
- Reduction by \( \lambda \) of voltage, intensity, and delay time (\( 1/f \sim CV/I \)).
- \( P' = (C/\lambda)(V^2/\lambda^2)(\lambda f) = P/\lambda^2 \) thus power density constant.
- Or can reduce \( V \) by less with better \( f \), but power increase.

End of Dennard scaling \( f \sim V - V_t \) (supply minus threshold voltage).
But leakage power not negligible if \( V_t \) too small.

- Frequency max around 2006 (\( \sim 4\text{GHz} \)).
- ILP, low-power CPU designs, multicore designs, GPUs.

More burden on the programmers & compilers.
The almost useless Amdahl’s law

See “A few bad ideas on the way to the triumph of parallel computing”, R. Schreiber, JPDC’14.

Amdahl’s law (1967)

- \( T_{\text{seq}} = s T_{\text{seq}} + (1 - s) T_{\text{seq}} \), with \( s \) fraction not parallelizable.
- With \( p \) proc., \( T_{\text{par}} / T_{\text{seq}} \geq s + (1 - s) / p \geq s \). Speed-up \( \leq 1 / s \).
The almost useless Amdahl’s law

See “A few bad ideas on the way to the triumph of parallel computing”, R. Schreiber, JPDC’14.

Amdahl’s law (1967)

- $T_{\text{seq}} = sT_{\text{seq}} + (1 - s)T_{\text{seq}}$, with $s$ fraction not parallelizable.
- With $p$ proc., $T_{\text{par}}/T_{\text{seq}} \geq s + (1 - s)/p \geq s$. Speed-up $\leq 1/s$.

Simplistic view: correct formula in wrong model ($\sim$ PRAM).

- Memory, comm., dedicated cores, program scaling, algorithmics!
- No insight even in favorable case, e.g., 2 independent purely sequential threads. Better: degree of parallelism, critical path, ratio comm./computation, data locality (spatial & temporal), bandwidth.
- But: make sure single core perf. remains good in parallel implem.
The almost useless Amdahl’s law

See “A few bad ideas on the way to the triumph of parallel computing”, R. Schreiber, JPDC’14.

Amdahl’s law (1967)  Useless except to show what it does not consider

- \( T_{\text{seq}} = sT_{\text{seq}} + (1 - s)T_{\text{seq}} \), with \( s \) fraction not parallelizable.
- With \( p \) proc., \( T_{\text{par}} / T_{\text{seq}} \geq s + (1 - s)/p \geq s \). Speed-up \( \leq 1/s \).

Simplistic view: correct formula in wrong model (\( \sim \) PRAM).

- Memory, comm., dedicated cores, program scaling, algorithmics!
- No insight even in favorable case, e.g., 2 independent purely sequential threads. Better: degree of parallelism, critical path, ratio comm./computation, data locality (spatial & temporal), bandwidth.
- But: make sure single core perf. remains good in parallel implem.
The almost useless Amdahl’s law

- But: make sure single core perf. remains good in parallel implem.

Gustafson’s law  Different reasoning, “scaling” programs.

- \( T_{\text{par}} = sT_{\text{par}} + (1 - s)T_{\text{par}} \), with \( s \) fraction of time in seq. core.
- With \( p \) proc., \( T_{\text{seq}} / T_{\text{par}} \geq s + (1 - s)p \). Speed-up \( \geq (1 - s)p \).
Where are we? HPC, embedded computing, accelerators

**Performance increase** how much is due to frequency increase, architecture improvements, compilers, algorithm design?

**Today's complications** Multi-level parallelism, memory hierarchy, bandwidth issues, attached accelerators, evolution in programming models.
Where are we? HPC, embedded computing, accelerators

Performance increase how much is due to frequency increase, architecture improvements, compilers, algorithm design?

Today's complications Multi-level parallelism, memory hierarchy, bandwidth issues, attached accelerators, evolution in programming models.

Compiler challenges

- PPPP Programmability, performance, portability, productivity.
- Virtualization New IRs, Just-in-time (JIT) compilation, runtimes.
- Maintenance Retargetable compilers, cleaner designs.
- Predictability Architecture design, worst-case execution time (WCET).
- Certification Correct-by-construction, verification, certified compilers.
- Languages Domain-specific languages, parallel languages.

New expectations, new compiler issues, but we can solve more. Automatic parallelization is unrealistic, but semi-automatic tools can help.
POLYHEDRAL COMPILATION
One view of history (borrowed from Steven Derrien)

Some actors of this evolution are here:
Multi-dimensional affine representation of loops and arrays

Matrix Multiply

```c
int i, j, k;
for (i = 0; i < n; i++) {
    for (j = 0; j < n; j++) {
        S: C[i][j] = 0;
        for (k = 0; k < n; k++) {
            T: C[i][j] += A[i][k] * B[k][j];
        }
    }
}
```

Instance-wise, element-wise, symbolic, parametric

Polyhedral Description

**Domain**

\[
\text{Domain} := [n] \rightarrow \{ S[i,j]: 0 \leq i,j < n; T[i,j,k]: 0 \leq i,j,k < n \};
\]

**Read**

\[
\text{Read} := [n] \rightarrow \{ T[i,j,k] \rightarrow A[i,k]; T[i,j,k] \rightarrow B[k,j]; T[i,j,k] \rightarrow C[i,j] \};
\]

**Write**

\[
\text{Write} := [n] \rightarrow \{ S[i,j] \rightarrow C[i,j]; T[i,j,k] \rightarrow C[i,j] \};
\]

**Order**

\[
\text{Order} := [n] \rightarrow \{ S[i,j] \rightarrow [i,j,0]; T[i,j,k] \rightarrow [i,j,1,k] \};
\]

Omega/ISCC syntax
Multi-dimensional affine representation of loops and arrays

Matrix Multiply

```c
int i, j, k;
for (i = 0; i < n; i++) {
    for (j = 0; j < n; j++) {
        S: C[i][j] = 0;
        for (k = 0; k < n; k++) {
            T: C[i][j] += A[i][k] * B[k][j];
        }
    }
}
```

Instance-wise, element-wise, symbolic, parametric

Polyhedral Description

```
Domain := [n]->{S[i,j]: 0<=i,j<n; T[i,j,k]: 0<=i,j,k<n};
Read := [n]->{T[i,j,k]->A[i,k]; T[i,j,k]->B[k,j]; T[i,j,k]->C[i,j]};
Write := [n]->{S[i,j]->C[i,j]; T[i,j,k]->C[i,j]};
Order := [n]->{S[i,j]->[i,j,0]; T[i,j,k]->[i,j,1,k]};
```

Omega/ISCC syntax

So, that's it?
Ex: PPCG code for CPU+GPU, GPU part

```c
__global__ void kernel0(float *A, float *B, float *C, int n) /* n=12288 */
{
    int b0 = blockIdx.y, b1 = blockIdx.x; /* Grid: 192x192 blocks, each with 32x32 threads */
    int t0 = threadIdx.y, t1 = threadIdx.x; /* Loops: 384x384x768 tiles, each with 32x32x16 points */
    __shared__ float shared_A[32][16]; /* Thus 1 block = 2x2x768 tiles, 1 thread = 1x1x16 points */
    __shared__ float shared_B[16][32];
    float private_C[1][1];

    for (int g1 = 32 * b0; g1 <= 12256; g1 += 6144) /* 6144 = 32 (tile size) x 192 (number of blocks) */
        for (int g3 = 32 * b1; g3 <= 12256; g3 += 6144) {
            private_C[0][0] = C[(t0 + g1) * 12288 + (t1 + g3)];
            for (int g9 = 0; g9 <= 12272; g9 += 16) { /* 16 consecutive points along k in a thread */
                if (t0 <= 15) /* 32x32 threads, only 16x32 do the transfer */
                    shared_B[t0][t1] = B[(t0 + g9) * 12288 + (t1 + g3)];
                if (t1 <= 15) /* 32x32 threads, only 32x16 do the transfer */
                    shared_A[t0][t1] = A[(t0 + g1) * 12288 + (t1 + g9)];
                __syncthreads();
                for (int c4 = 0; c4 <= 15; c4 += 1) /* compute the 16 consecutive points along k */
                    private_C[0][0] += (shared_A[t0][c4] * shared_B[c4][t1]);
                __syncthreads();
            }
            C[(t0 + g1) * 12288 + (t1 + g3)] = private_C[0][0];
            __syncthreads();
        }
}
```

PPCG compiler (Parkas)
Verdoolaege, Cohen, etc.
__global__ void kernel0(float *A, float *B, float *C, int n) /* n=12288 */
{
    int b0 = blockIdx.y, b1 = blockIdx.x; /* Grid: 192x192 blocks, each with 16x16 threads */
    int t0 = threadIdx.y, t1 = threadIdx.x; /* Loops: 384x384x768 tiles, each with 32x32x16 points */
    __shared__ float shared_A[32][16]; /* Thus 1 block = 2x2x768 tiles, 1 thread = 2x2x16 points */
    __shared__ float shared_B[16][32];
    float private_C[2][2];

    for (int g1 = 32 * b0; g1 <= 12256; g1 += 6144) /* 6144 = 32 (tile size) x 192 (number of blocks) */
        for (int g3 = 32 * b1; g3 <= 12256; g3 += 6144) {
            private_C[0][0] = C[(t0 + g1) * 12288 + (t1 + g3)]; /* 2x2 points unrolled for register usage */
            private_C[0][1] = C[(t0 + g1) * 12288 + (t1 + g3 + 16)];
            private_C[1][0] = C[(t0 + g1 + 16) * 12288 + (t1 + g3)];
            private_C[1][1] = C[(t0 + g1 + 16) * 12288 + (t1 + g3 + 16)];

            for (int g9 = 0; g9 <= 12272; g9 += 16) { /* 16 consecutive points along k in a thread */
                for (int c1 = t1; c1 <= 31; c1 += 16) /* 16x32 to bring with 16x16 threads */
                    shared_B[t0][c1] = B[(t0 + g9) * 12288 + (g3 + c1)];
                for (int c0 = t0; c0 <= 31; c0 += 16) /* 32x16 to bring with 16x16 threads */
                    shared_A[c0][t1] = A[(g1 + c0) * 12288 + (t1 + g9)];
            }
            __syncthreads();

            for (int c2 = 0; c2 <= 15; c2 += 1) { /* unrolled for register usage */
                private_C[0][0] += (shared_A[t0][c2] * shared_B[c2][t1]);
                private_C[0][1] += (shared_A[t0][c2] * shared_B[c2][t1 + 16]);
                private_C[1][0] += (shared_A[t0 + 16][c2] * shared_B[c2][t1]);
                private_C[1][1] += (shared_A[t0 + 16][c2] * shared_B[c2][t1 + 16]);
            }
            __syncthreads();
        }
    C[(t0 + g1) * 12288 + (t1 + g3)] = private_C[0][0];
    C[(t0 + g1) * 12288 + (t1 + g3 + 16)] = private_C[0][1];
    C[(t0 + g1 + 16) * 12288 + (t1 + g3)] = private_C[1][0];
    C[(t0 + g1 + 16) * 12288 + (t1 + g3 + 16)] = private_C[1][1];
    __syncthreads();
}
Typical criticism against polyhedral techniques

Too hard to understand

Heavy formalism

No such codes

Not worth the effort
Typical criticism against polyhedral techniques

Too hard to understand

- Easier now with demonstrators, compilers (e.g., PIPS, Pluto, PPCG, LLVM support), tutorials, and schools.

Not worth the effort
- Often the right limit for automation. Key for many analyses & optimizations, not just loop transformations. Growing industrial interest.

Key to reason on multi-dimensional computations and data structures, and avoid explicit unrolling. More applications to come (e.g., loop termination, parallel languages, verification/certification, WCET).
(Parametric) analysis, transformations, optimizations

Loop transformations
- Automatic parallelization.
- Transformations framework.
- Scanning & code generation.
- Dynamic & speculative opt.

Instance/element-wise analysis
- Single assignment.
- Liveness, array expansion/reuse.
- Analysis of parallel programs.
- Data races & deadlocks detection.

Mapping computations & data
- Systolic arrays design.
- Data distribution.
- Communication opt.
- Streams optimizations.

Counting, (de-)linearizing
- Cache misses.
- FIFOs, array linearizations.
- Memory size computations.
- Loop termination (e.g., WCET).

Basic form: affine bounds and array access functions

Fortran DO loops:
Affine bounds of surrounding counters & parameters.

DO i=1, N
  DO j=1, N
    S: a(i,j) = c(i,j-1)
    T: c(i,j) = a(i,j) + a(i-1,N)
  ENDDO
ENDDO

- Multi-dimensional arrays, same restriction for access functions.
- Loop increment = 1.
- Iteration domain: polyhedron.
- Iteration vector \( (i,j) \).
- Lexico. order: \( S(i,j) \rightarrow (i,j,0) \), \( T(i,j) \rightarrow (i,j,1) \).
Basic form: affine bounds and array access functions

**Fortran DO loops:**

Affine bounds of surrounding counters & parameters.

```fortran
DO i=1, N
    DO j=1, N
        S: a(i,j) = c(i,j-1)
        T: c(i,j) = a(i,j) + a(i-1,N)
    ENDDO
ENDDO
```

- Multi-dimensional arrays, same restriction for access functions.
- Loop increment = 1.
- Iteration domain: polyhedron.
- **Iteration vector** \((i,j)\).
- Lexico. order: \(S(i,j) \rightarrow (i,j,0)\), \(T(i,j) \rightarrow (i,j,1)\).

**Polyhedral transformation**

```
\sum_{i=1}^{n} \sum_{j=i}^{n} u_{i,j} = \sum_{j=1}^{n} \sum_{i=1}^{j} u_{i,j}
```

**Set of nested affine loops**

**Parsing and analyzing**

**Scanning polyhedra with loops**

**Polyhedral transformation**

**Polyhedral representation**
Why loops? Repetitive structures, hot spots

**DO loops**: few lines for a (possibly) large set of regular computations.

- Smaller code size.
- Repetitive structure: regularity that can be exploited.
- Hot parts of codes where optimizations are needed.
- Large potential for optimizations (e.g., parallelism, memory usage).
- Algorithms complexity depends on code size, not computations size.
- Parametric loops, needed for “optimality” w.r.t. unroll version.
- Abstraction between low-level (hardware) & high-level (program).

**Arrays**: similar properties for multi-dimensional storage.

- To be exploited: structure, parameters, symbolic unrolling.
Be careful: different types of codes with loops

**Fortran DO loops:**

```fortran
DO i=1, N
   DO j=1, N
      a(i,j) = c(i,j-1)
      c(i,j) = a(i,j) + a(i-1,N)
   ENDDO
ENDDO
```

**C for loops:**

```c
for (i=1; i<=N; i++) {
   for (j=1; j<=N; j++) {
      a[i][j] = c[i][j-1];
      c[i][j] = a[i][j] + a[i-1][N];
   }
}
```

**C for and while loops:**

```c
y = 0; x = 0;
while (x <= N && y <= N) {
   if (?) {
      x=x+1;
      if (y >= 0 && ?) y=y-1;
   }
   y=y+1;
}
```

**Uniform recurrence equations**

\[ \forall (i, j) \text{ such that } 1 \leq i, j \leq N \]

\[
\begin{align*}
  a(i,j) &= c(i,j - 1) \\
  b(i,j) &= a(i - 1,j) + b(i,j + 1) \\
  c(i,j) &= a(i,j) + b(i,j)
\end{align*}
\]
More types of codes with loops

Manipulation of integer sets, Presburger arithmetic, counting

Chernikova, Ehrhart, Barvinok, quasi-polynomials

In many cases, no need to really understand the theory anymore ❄️ ISL
\[
\min\{c.x \mid Ax \geq b, \, x \geq 0\} = \max\\{y.b \mid yA \leq c, \, y \geq 0\}
\]

\[
\begin{align*}
\min \quad & 11t + 10u \quad | \\
\quad & 2t + 3u \geq 5 \\
\quad & 3t + 2u \geq 4 \\
\quad & 5t + u \geq 12 \\
\quad & t \geq 0, \, u \geq 0
\end{align*} = \quad \max \quad \begin{align*}
\quad & 5x + 4y + 12z \quad | \\
\quad & 2x + 3y + 5z \leq 11 \\
\quad & 3x + 2y + z \leq 10 \\
\quad & x \geq 0, \, y \geq 0, \, z \geq 0
\end{align*}
\]

**Primal problem**: doped athlete buy the right numbers \( t \) and \( u \) of doping pills (with unit price 11 and 10) to get a sufficient intake (5, 4, and 12) of 3 elementary products, knowing the content of each mixed product.

**Dual problem**: dealer sell the 3 elementary products at maximal price, while being cheaper than doping pills.
\[
\min\{c.x \mid Ax \geq b, \ x \geq 0\} = \max\{y.b \mid yA \leq c, \ y \geq 0\}
\]

\[
\begin{align*}
\min \quad & 11t + 10u \\
\quad & 2t + 3u \geq 5 \\
\quad & 3t + 2u \geq 4 \\
\quad & 5t + u \geq 12 \\
\quad & t \geq 0, \ u \geq 0 \\
\end{align*}
\]

\[
\begin{align*}
\max \quad & 5x + 4y + 12z \\
\quad & 2x + 3y + 5z \leq 11 \\
\quad & 3x + 2y + z \leq 10 \\
\quad & x \geq 0, \ y \geq 0, \ z \geq 0 \\
\end{align*}
\]

Primal problem: doped athlete buy the right numbers \(t\) and \(u\) of doping pills (with unit price 11 and 10) to get a sufficient intake (5, 4, and 12) of 3 elementary products, knowing the content of each mixed product.

Dual problem: dealer sell the 3 elementary products at maximal price, while being cheaper than doping pills.

Complexity

- Optimal rational solution: polynomial (L. Khachiyan).
- Optimal integer solution: NP-complete and inequality only.
- Simplex algorithm (fast in practice), basis reduction (Lenstra et al.), parametric linear programming (P. Feautrier).
Example of Sven Verdoolaege’s iscc script

```c
# void polynomial_product(int n, int *A, int *B, int *C) {
#   for(int k = 0; k < 2*n-1; k++)
#     S: C[k] = 0;
#   for(int i = 0; i < n; i++)
#     for(int j = 0; j < n; j++)
#       T: C[i+j] += A[i] * B[j];
# }
```

Domain := [n] -> {
  S[k] : k <= -2 + 2n and k >= 0;
  T[i, j] : i >= 0 and i <= -1 + n and j <= -1 + n and j >= 0;
};

Read := [n] -> {
  T[i, j] -> C[i + j]; T[i, j] -> B[j]; T[i, j] -> A[i];
} * Domain;

Write := [n] -> {
  S[k] -> C[k]; T[i, j] -> C[i + j];
} * Domain;

Schedule := [n] -> {
  T[i, j] -> [1, i, j]; S[k] -> [0, k, 0];
};
Example of Sven Verdoolaege’s iscc script (Cont’d)

Schedule := [n] -> {
    T[i, j] -> [1, i, j]; S[k] -> [0, k, 0];
};

### Happens-Before relation without syntactic sugar equivalent to:
# Before := Schedule << Schedule;

Lexico := { [i0,i1,i2] -> [j0,j1,j2] : i0 < j0 or (i0 = j0 and i1 < j1)
            or (i0 = j0 and i1 = j1 and i2 < j2) }

Before := Schedule . Lexico . (Schedule^-1)
print Before;

We get the strict sequential order of operations in the program:

[n] -> { S[k] -> T[i, j]; S[k] -> S[k’] : k’ > k;
        T[i, j] -> T[i’, j’] : i’ > i; T[i, j] -> T[i, j’] : j’ > j }

RaW := (Write . (Read^-1)) * Before;
print RaW;

We get the read-after-write memory-based data dependences:

[n] -> { S[k] -> T[i, k - i] : 0 <= k <= -2 + 2n and i >= 0 and
         -n + k < i <= k and i < n;
         T[i, j] -> T[i’, i + j - i’] : 0 <= i < n and 0 <= j < n and i’ > i
         and i’ >= 0 and -n + i + j < i’ <= i + j and i’ < n }
Some iscc features and syntax with sets and relations/maps

+, -, * union, difference, intersection. domain m, range m set from map.
m(s) apply map to set. m1.m2 join of maps.
s1 cross s2, m1 cross m2 cartesian product. deltas m set of differences.
coefficients s constraints for Farkas lemma.
lexmin s, lexmin m lexicographic minimum, same for max.
codegen s, codegen m scanning domain (following map m). Example:

codegen RaW;
for (int c0 = 0; c0 < n; c0 += 1)
    for (int c1 = 0; c1 < n; c1 += 1) {
        for (int c2 = max(0, -n + c0 + c1 + 1); c2 < c0; c2 += 1)
            T(c2, c0 + c1 - c2);
        S(c0 + c1);
    }

card s, card m Number of integer points in set or image. Example:

print card RaW;
[n] -> { S[k] -> ((-1 + 2 * n) - k) : n <= k <= -2 + 2n;
       S[k] -> (1 + k) : 0 <= k < n;
       T[i, j] -> ((-1 + n) - i) : i <= -2 + n and n - i <= j < n;
       T[i, j] -> j : i >= 0 and 0 < j < n - i }
Courses in 2013 polyhedral spring school

See the thematic quarter on compilation http://labexcompilation.ens-lyon.fr/ for polyhedral spring school and keynotes on HPC languages.

S. Rajopadhye  A view on history.
P. Feautrier  “Basics” in terms of mathematical concepts.
L.-N. Pouchet  Polyhedral loop transformations, scheduling.
S. Verdoolaege  Integer sets & relations: high-level modeling and implem.
A. Miné  Program invariants and abstract interpretation.
B. Creusillet  Array region analysis and applications.
U. Bondhugula (+ A. Darte)  Compil. for distr. memory, memory mapping.
Sadayappan (+ N. Vasilache)  Polyhedral transf. for SIMD architectures.

CLASSIC LOOP
TRANSFORMATIONS
Catalog of loop and array transformations

Loop unrolling (by constant factor)
Software pipelining
Loop fusion/distribution
Loop peeling(statement) sinking
loop shifting (retiming)
Loop interchange
Loop skewing (by constant factor)
Loop reversal
Unimodular transformation
Affine transformation

Strip mining (by parametric factor)
Unroll-and-jam
Loop tiling
Scalar privatization/expansion
Single assignment expansion
Array unrolling
Array padding
Array linearization
Array contraction
Affine modulo allocation
Partial and total loop unrolling

DO i=1, 10
    a(i) = b(i)
    d(i) = a(i-1)
ENDDO

Unrolling by 2

DO i=1, 10, 2
    a(i) = b(i)
    d(i) = a(i-1)
    a(i+1) = b(i+1)
    d(i+1) = a(i)
ENDDO

Partial unrolling

- Replicates instructions to improve schedule & resource usage.
- Can be used for array scalarization.
- Increases code size and (indirectly) register usage.

Total loop unrolling

- Flattens the loops and changes structure.
Strip mining, loop coalescing

DO i=1, N
    a(i) = b(i) + c(i)
ENDDO

Strip mining

DO \( l_s = 1, N, s \)
    a(i) = b(i) + c(i)
ENDDO

Loop linearization

Strip mining
- Performs parametric loop unrolling.
- Changes the structure (2D space).
- Creates blocks of computations.
- Can be used as a preliminary step for tiling.

Loop linearization
- Can reduce the control of loops.
- Reduces the problem dimension.
Software pipelining and modulo scheduling

Optimize **throughput**, with dependence & resource constraints. Cyclic dependence graph with iteration distance (+ latency information). Ex: sequential, pipelined LANai3.0, load & branch = one “shadow”.

Sequential code

```assembly
L400:
   ld[r26] → r27
   nop
   add r27, 6740 → r26
   ld 0x1A54[r27] → r27
   nop
   sub.f r27, r25 → r0
   bne L400
   nop
L399:
```

$8n$ cycles.
Software pipelining and modulo scheduling

</tr>
</tbody>
</table>

\[ \sigma(S, i) = \lambda.i + \rho_S = \lambda.(i + q_S) + r_S \text{ with } 0 \leq r_S < \lambda \text{ i.e., } r_S = \rho_S \mod \lambda \]

Modulo scheduling: initiation interval (1/throughput). Here \( \lambda = 5 \).
Loop shifting or retiming

DO  i=1, N
    a(i) = b(i)
    d(i) = a(i-1)
ENDDO

Loop shifting

DO  i=0, N
    IF (i > 0) THEN
        a(i) = b(i)
    IF (i < N) THEN
        d(i+1) = a(i)
ENDDO

Here: dependence at distance 1 (loop-carried or inter-iteration) transformed into dependence at distance 0 (loop-independent or intra-iteration).

Main features

- Similar to software pipelining.
- Creates prelude/postlude or introduces if statements.
- Can be used to align accesses and enable loop fusion.
- Particularly suitable to handle constant dependence distances.
Loop peeling and statement sinking

DO i=0, N
    IF (i > 0) THEN
        a(i) = b(i)
    ENDIF
    IF (i < N) THEN
        d(i+1) = a(i)
    ENDIF
ENDDO

d(1) = a(0)
DO i=1, N-1
    a(i) = b(i)
    d(i+1) = a(i)
ENDDO
    a(N) = b(N)

Loop peeling
- Removes a few iterations to make code simpler.
- May enable more transformations.
- Reduces the iteration domain (range of loop counter).

Statement sinking
- Used to make loops perfectly nested.
Loop distribution and loop fusion

DO i=1, N
  a(i) = b(i)
  d(i) = a(i-1)
ENDDO

Loop distribution

DO i=1, N
  a(i) = b(i)
ENDDO

DO i=1, N
  d(i) = a(i-1)
ENDDO

Loop fusion

Here: intra-loop dependence transformed into inter-loop dependence.

Loop distribution
- Used to parallelize/vectorize loops (no inter-iteration dependence).
- Valid if statements not involved in a circuit of dependences.
- Parallelization: separate strongly connected components.

Loop fusion
- Increases the granularity of computations.
- Reduces loop overhead.
- Usually improves spatial & temporal data locality.
- May enable array scalarization.

\quad \quad a(i,j) &= b(i-1,j-1)
\end{align*}
\]

这些问题非常具体，但仍然显示了将依赖关系“推”到内部的困难，即优化局部性。
Is there some **loop parallelism** (i.e., parallel loop iterations) in the following two codes? What is their **degree of parallelism**?

\[
\begin{align*}
\text{DO } & i=1, N \\
& \quad \text{DO } j=1, N \\
& \quad \quad a(i,j) = c(i,j-1) \\
& \quad \quad c(i,j) = a(i,j) + a(i-1,N) \\
& \quad \text{ENDDO} \\
& \text{ENDDO}
\end{align*}
\]
Is there some loop parallelism (i.e., parallel loop iterations) in the following two codes? What is their degree of parallelism?

```fortran
DO i=1, N
  DO j=1, N
    a(i,j) = c(i,j-1)
    c(i,j) = a(i,j) + a(i-1,N)
  ENDDO
ENDDO
```

```fortran
DO i=1, N
  DO j=1, N
    a(i,j) = c(i,j-1)
    c(i,j) = a(i,j) + a(i-1,j)
  ENDDO
ENDDO
```
Loop interchange

Loop interchange: \((i, j) \mapsto (j, i)\).

\[
\begin{align*}
\text{DO } & i=1, N \\
\text{DO } & j=1, i \\
& a(i,j+1) = a(i,j) + 1 \\
\text{ENDDO} \\
\text{ENDDO}
\end{align*}
\]

\[
\begin{align*}
\text{DO } & j=1, N \\
\text{DO } & i=j, N \\
& a(i,j+1) = a(i,j) + 1 \\
\text{ENDDO} \\
\text{ENDDO}
\end{align*}
\]

Here: dependence distance \((0, 1)\) transformed into distance \((1, 0)\).

Main features

- May involve bounds computations as in \(\sum_{i=1}^{n} \sum_{j=1}^{i} S_{i,j} = \sum_{j=1}^{n} \sum_{i=j}^{n} S_{i,j}\).
- Can impact loop parallelism.
- Basis of loop tiling.
- Changes order of memory accesses and thus data locality.
Unroll-and-jam

DO $i = 1, 2N$
    DO $j = 1, M$
        $a(i,j) = \ldots$
    ENDDO
ENDDO

Do $i = 0, 2N, 2$
    DO $j = 0, M$
        $a(i,j) = \ldots$
        $a(i+1,j) = \ldots$
    ENDDO
ENDDO

Interests:
- Combines outer loop unrolling and loop fusion.
- Changes order of iterations and locality, keeping same loop nesting.
- Can be viewed as a restricted form of tiling $s \times 1$. 
Loop reversal and loop skewing

Loop reversal:  $i \mapsto -i$, loop executed in opposite order.

Loop skewing:  $(i, j) \mapsto (i, j + i)$, loop iterations in the same order.

```
DO i=1, N
  DO j=1, N
    a(i,j-1) = a(i-1,j) + 1
  ENDDO
ENDDO
```

```
DO i=1, N
  DO j=1+i, N+i
    a(i,j-i-1) = a(i-1,j-i) + 1
  ENDDO
ENDDO
```

Skewing by 1

Skewing by $-1$

Dependence distance $(1, -1)$ transformed into distance $(1, 0)$. 
Unimodular transf.: reversal + skewing + interchange

Here, \((i, j) \mapsto (t, p) = (i + j, i)\). Loop bounds with Fourier-Motzkin elim.:

\[
1 \leq i, j \leq N \iff 1 \leq p, t - p \leq N \iff 1 \leq p \leq N, \ t - N \leq p \leq t - 1
\]

Elimination of \(p\) \(\Rightarrow\) \(2 \leq t \leq 2N, 1 \leq N\), Elimination of \(t\) \(\Rightarrow\) \(1 \leq N\)
Unimodular transf.: reversal + skewing + interchange

DO i=1, N
   DO j=1, N
      a(i,j) = ...  
   ENDDO
ENDDO

Unimodular $U$  
$\rightarrow$

DO t=2, 2N
   DO p=max(1,t-N), min(N,t-1)
      a(p,t-p) = ...  
   ENDDO
ENDDO

Unimodular $U^{-1}$  
$\leftarrow$

Here, $(i, j) \mapsto (t, p) = (i + j, i)$. Loop bounds with Fourier-Motzkin elim.: 

$1 \leq i, j \leq N \iff 1 \leq p, t – p \leq N \iff 1 \leq p \leq N, t – N \leq p \leq t – 1$

Elimination of $p$ $\Rightarrow$ $2 \leq t \leq 2N, 1 \leq N$, Elimination of $t$ $\Rightarrow$ $1 \leq N$

In general:  
“For all $\vec{i} \in \mathcal{P}$ do $S(\vec{i})$” $\rightarrow$ “For all $\vec{p} \in U \mathcal{P}$ do $S(U^{-1} \vec{p})$”.

$\begin{pmatrix} t \\ p \end{pmatrix} = U \begin{pmatrix} i \\ j \end{pmatrix} \quad \begin{pmatrix} i \\ j \end{pmatrix} = U^{-1} \begin{pmatrix} t \\ p \end{pmatrix}$

Here
$U = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$
$U^{-1} = \begin{pmatrix} 0 & 1 \\ 1 & -1 \end{pmatrix}$

New implicit execution order: iterate lexicographically on $(t, p)$.
If $S(\vec{i})$ depends on $T(\vec{j})$, dep. distance $d = \vec{i} – \vec{j}$ lexico-positive: $\vec{d} \succeq_{\text{lex}} \vec{0}$.
New distance $\vec{d}' = U(\vec{i} – \vec{j}) = U\vec{d}$. Validity condition: $\vec{d}' = U\vec{d} \succeq_{\text{lex}} \vec{0}$.
DO t=2, 2N
   DOPAR j = max(1, t-N), min(N, t-1)
      a(t-j,j) = c(t-j, j-1)
      c(t-j,j) = a(t-j,j) + a(t-j-1,j)
   ENDDO
ENDDO

DO I=1, N, B
   DO J=1, N, B
      DO i = I, min(I+B-1, N)
         DO j = J, min(J+B-1, N)
            a(i,j) = c(i,j-1)
            c(i,j) = a(i,j) + a(i-1,j)
         ENDDO
      ENDDO
   ENDDO
ENDDO
ENDDO
ENDDO

⚠️ Tiling and parallelism detection: similar problem.
In practice, need to combine all. Ex: HLS with C2H Altera

Optimize DDR accesses for bandwidth-bound accelerators.

- Use tiling for **data reuse** and to enable **burst communication**.
- Use fine-grain software pipelining to **pipeline DDR requests**.
- Use double buffering to **hide DDR latencies**.
- Use coarse-grain software pipelining to **hide computations**.

Note:

- Dependence synchro.
- DDR access synchro.

Load(T) at time 2T
Comp(T) at time 2T+2
Store(T) at time 2T+5
SYSTEMS OF UNIFORM RECURRENCE EQUATIONS
SURE: system of uniform recurrence equations (1967)

∀\vec{p} \in \{\vec{p} = (i, j) \mid 1 \leq i, j \leq N\}

\begin{align*}
  a(i, j) &= c(i, j - 1) \\
  b(i, j) &= a(i - 1, j) + b(i, j + 1) \\
  c(i, j) &= a(i, j) + b(i, j)
\end{align*}

- RDG (reduced dependence graph) $G = (V, E, \vec{w})$.
- EDG (expanded dep. graph): vertices $V \times \mathcal{P} = \text{unrolled RDG}$.

Semantics:
- Explicit dependences, implicit schedule.
- Compute left-hand side first, unless not in $\mathcal{P}$ (input data).
Two main problems: computability & scheduling

Computability (KMW view) A SURE is computable for all bounded domains $P$ if and only if the RDG has no cycle $C$ with $\vec{w}(C) = \vec{0}$.

Scheduling (dual view): Lamport, Feautrier, etc. How to find an explicit schedule? With guaranteed "latency"?

Looking for an elementary cycle of zero weight: NP-complete.
Looking for a multi-cycle of zero weight: polynomial.
Looking for a cycle of zero weight: polynomial.
Two main problems: computability & scheduling

Computability (KMW view) A SURE is computable for all bounded domains $P$ if and only if the RDG has no cycle $C$ with $\vec{w}(C) = \vec{0}$.  

Scheduling (dual view): Lamport, Feautrier, etc. How to find an explicit schedule? With guaranteed “latency”?  

Looking for an elementary cycle of zero weight: NP-complete.  
Looking for a multi-cycle of zero weight: polynomial.  
Looking for a cycle of zero weight: polynomial.

Key structure: the subgraph $G'$ induced by all edges that belong to a multi-cycle (i.e., union of cycles) of zero weight.

$G$:  
\[
\begin{array}{c}
\text{a} \\
\downarrow 1 \\
\downarrow 0 \\
\text{b} \\
\downarrow 0 \\
\downarrow -1 \\
\end{array}
\quad

\begin{array}{c}
\text{c} \\
\downarrow 0 \\
\downarrow 1 \\
\end{array}
\]

$G$ and $G'$:
Key properties for multi-dimensional decomposition

Lemma (Look in $G'$)
A zero-weight cycle is a zero-weight multi-cycle.
» Look in the subgraph $G'$ only.

Note: clear, but how to compute $G'$?

Lemma (Look in each SCC)
A zero-weight cycle belongs to a strongly connected component.
» Look in each strongly connected component (SCC) separately.

Note: this is the recursive step.

Lemma (End of recursion)
If $G'$ is strongly connected, there is a zero-weight cycle.
» This stops the recursion.
Lemma (End of recursion)

If $G'$ is strongly connected, there is a zero-weight cycle.

- $\sum_i e_i$ cycle that visits all vertices.
- $e_i$ in multi-cycle $C_i$, with $\mathbf{\tilde{w}}(C_i) = \mathbf{0}$.
- $C_i = e_i + P_i + C'_i$.
- Follow the $e_i$, then the $P_i$ and, on the way, plug the $C'_i$. 

Key properties for multi-dimensional decomposition
Karp, Miller, and Winograd’s decomposition

Boolean KMW(G):

- Build $G'$ the subgraph of zero-weight multicycles of $G$.
- Compute $G'_1, \ldots, G'_s$, the $s$ SCCs of $G'$.
  - If $s = 0$, $G'$ is empty, return TRUE.
  - If $s = 1$, $G'$ is strongly connected, return FALSE.
  - Otherwise return $\wedge_i \text{KMW}(G'_i)$ (logical AND).

Then, $G$ is computable iff KMW($G$) returns TRUE.
Karp, Miller, and Winograd’s decomposition

Boolean KMW($G$):
- Build $G'$ the subgraph of zero-weight multicycles of $G$.
- Compute $G'_1, \ldots, G'_s$, the $s$ SCCs of $G'$.
  - If $s = 0$, $G'$ is empty, return TRUE.
  - If $s = 1$, $G'$ is strongly connected, return FALSE.
  - Otherwise return $\land_i \text{KMW}(G'_i)$ (logical AND).

Then, $G$ is computable iff KMW($G$) returns TRUE.

Depth $d = 0$ if $G$ acyclic, $d = 1$ if all SCCs have an empty $G'$, etc.

Theorem (Depth of the decomposition)

*If $G$ is computable, $d \leq n$ (dimension of $P$). Otherwise, $d \leq n + 1$.*

Theorem (Optimal number of parallel loops)

*If $\Omega(N) \subseteq P \subseteq O(N)$, there is a dependence path of length $\Omega(N^d)$ and one can build an affine schedule of latency $O(N^d)$ “optimal”*
But how to compute $G'$? Primal and dual programs.

e \in G' \iff v_e = 0 \text{ in any optimal solution of the linear program:}

$$\min \left\{ \sum_e v_e \mid \vec{q} \geq \vec{0}, \vec{v} \geq \vec{0}, \vec{q} + \vec{v} \geq \vec{1}, C\vec{q} = \vec{0}, W\vec{q} = \vec{0} \right\}$$

Always interesting to take a look at the dual program:

$$\max \left\{ \sum_e z_e \mid \vec{0} \leq \vec{z} \leq \vec{1}, X.\vec{w}(e) + \rho_v - \rho_u \geq z_e, \forall e = (u, v) \in E \right\}$$
But how to compute $G'$? Primal and dual programs.

$e \in G'$ iff $v_e = 0$ in any optimal solution of the linear program:

$$\min \left\{ \sum_e v_e \mid \vec{q} \geq \vec{0}, \quad \vec{v} \geq \vec{0}, \quad \vec{q} + \vec{v} \geq \vec{1}, \quad C\vec{q} = \vec{0}, \quad W\vec{q} = \vec{0} \right\}$$

Always interesting to take a look at the dual program:

$$\max \left\{ \sum_e z_e \mid \vec{0} \leq \vec{z} \leq \vec{1}, \quad \vec{X}.\vec{w}(e) + \rho_v - \rho_u \geq z_e, \quad \forall e = (u, v) \in E \right\}$$

Generalizes modulo scheduling: $\sigma(u, \vec{p}) = \vec{X}.\vec{p} + \rho_u$ (in 1D: $\lambda.\vec{p} + \rho_u$).

For any optimal solution:

- $e \notin G' \iff \vec{X}.\vec{w}(e) + \rho_v - \rho_u \geq 1$  \hspace{1cm} \(\heartsuit\) loop carried.
- $e \in G' \iff \vec{X}.\vec{w}(e) + \rho_v - \rho_u = 0$ \hspace{1cm} \(\heartsuit\) loop independent.

and keep going until all dependences become carried.

\(\heartsuit\) Multi-dimensional scheduling and loop transformations.
Scheduling/parallelization of illustrating example

∀\vec{p} \in \{\vec{p} = (i, j) \mid 1 \leq i, j \leq N\}

\{ 
  a(i, j) = c(i, j - 1) 
  b(i, j) = a(i - 1, j) + b(i, j + 1) 
  c(i, j) = a(i, j) + b(i, j) 
\}

\vec{X}_1.(0, 1) = 0 \quad \vec{X}_1.(1, 0) \geq 2 \quad \Rightarrow \quad \vec{X}_1 = (2, 0), \quad \rho_a = 1 \quad \rho_b = 0, \quad \rho_c = 1

Final schedule
\{ 
  \sigma_a(i, j) = (2i + 1, 2j) 
  \sigma_b(i, j) = (2i, -j) 
  \sigma_c(i, j) = (2i + 1, 2j + 1) 
\}

\end{align*}

Final schedule
\[
\begin{align*}
\sigma_a(i, j) &= (2i + 1, 2j) \\
\sigma_b(i, j) &= (2i, -j) \\
\sigma_c(i, j) &= (2i + 1, 2j + 1)
\end{align*}
\]

DETECTION OF LOOP PARALLELISM
Back to DO loops: dependence distances

Fortran DO loops:
- Explicit schedule
- Implicit dependences
- EDG: $S(\vec{i}) \Rightarrow T(\vec{j})$.
- RDG: $S \rightarrow T$.

```
DO i=1, N
  DO j=1, N
    a(i,j) = ... 
    b(i,j) = a(j,i) + 1
  ENDDO
ENDDO
```

Pair set $R_{S,T} = \{(\vec{i},\vec{j}) \mid S(\vec{i}) \Rightarrow T(\vec{j})\}$

Affine dep. $\vec{i} = f(\vec{j})$ when possible.

Distances $E_{S,T} = \{(\vec{j} - \vec{i}) \mid S(\vec{i}) \Rightarrow T(\vec{j})\}$.

Over-approx. $\overline{E}_{S,T}$ s.t. $E_{S,T} \subseteq \overline{E}_{S,T}$:
- affine relation
- polyhedron: vertices, rays, lines
- direction vector: $\mathbb{Z}$, $+$, $-$, $*$
- dependence level: $1$, $2$, $\ldots$, $\infty$
Back to DO loops: dependence distances

Fortran DO loops:
- Explicit schedule
- Implicit dependences
- EDG: $S(\vec{i}) \Rightarrow T(\vec{j})$
- RDG: $S \rightarrow T$

```
DO i=1, N
  DO j=1, N
    a(i,j) = ...
    b(i,j) = a(j,i) + 1
  ENDDO
ENDDO
```

Pair set $R_{S,T} = \{(\vec{i},\vec{j}) \mid S(\vec{i}) \Rightarrow T(\vec{j})\}$

Affine dep. $\vec{i} = f(\vec{j})$ when possible.

Distances $E_{S,T} = \{(\vec{j} - \vec{i}) \mid S(\vec{i}) \Rightarrow T(\vec{j})\}$.

Here: $E = \left\{ \left( \begin{array}{c} i - j \\ j - i \end{array} \right) \mid i - j \geq 1, \ 1 \leq i, j \leq N \right\}$

Over-approx. $\overline{E}_{S,T}$ s.t. $E_{S,T} \subseteq \overline{E}_{S,T}$:
- affine relation
- polyhedron: vertices, rays, lines
- direction vector: $\mathbb{Z}$, $+$, $-$, $*$
- dependence level: 1, 2, ..., $\infty$

Polyhedral approximation: $E' = \left\{ \left( \begin{array}{c} 1 \\ -1 \end{array} \right) + \lambda \left( \begin{array}{c} 1 \\ -1 \end{array} \right) \mid \lambda \geq 0 \right\}$

Direction vector: $E' = \left( \begin{array}{c} + \\ - \end{array} \right) = \left\{ \left( \begin{array}{c} 1 \\ -1 \end{array} \right) + \lambda \left( \begin{array}{c} 1 \\ 0 \end{array} \right) + \mu \left( \begin{array}{c} 0 \\ -1 \end{array} \right) \mid \lambda, \mu \geq 0 \right\}$

Level: $E' = \left( \begin{array}{c} + \\ * \end{array} \right) = \left\{ \left( \begin{array}{c} 1 \\ 0 \end{array} \right) + \lambda \left( \begin{array}{c} 1 \\ 0 \end{array} \right) + \mu \left( \begin{array}{c} 0 \\ 1 \end{array} \right) \mid \lambda \geq 0 \right\}$
Uniformization of dependences: example

DO i=1, N
  DO j=1, N
    S: a(i,j) = c(i,j-1)
    T: c(i,j) = a(i,j) + a(i-1,N)
  ENDDO
ENDDO

S(i-1,N) ⇒ T(i,j)
Dep. distance (1, j − N).
Uniformization of dependences: example

\[
\text{DO } i=1, N \\
\quad \text{DO } j=1, N \\
\quad \quad \text{S: } a(i,j) = c(i,j-1) \\
\quad \quad \text{T: } c(i,j) = a(i,j) + a(i-1,N) \\
\text{ENDDO} \\
\text{ENDDO}
\]

\[S(i-1,N) \Rightarrow T(i,j)\]

Dep. distance \((1, j - N)\).

Direction vector \((1, 0-) = (1, 0) + k(0, -1), k \geq 0\)

\(\text{SURE! KMW!}\)

No parallelism \(d = 2\). Code appears purely sequential (and here it is).
Second example with direction vectors

DO i = 1, N
  DO j = 1, N
    DO k = 1, j
      S1: a(i,j,k) = c(i,j,k-1) + 1
      S2: b(i,j,k) = a(i-1,j+i,k) + b(i,j-1,k)
      S3: c(i,j,k+1) = c(i,j,k) + b(i,j-1,k+i) + a(i,j-k,k+1)
    ENDDO
  ENDDO
ENDDO
Second example: dependence graphs

Initial RDG.

Uniformized RDG.
Second example: $G$ and $G'$

Uniformized RDG.  

$(2i, j)$ for $S_2$, $(2i + 1, 2k)$ for $S_1$, and $(2i + 1, 2k + 3)$ for $S_3$. 
DOSEQ i=1, n
   DOSEQ j=1, n /* scheduling (2i, j) for S2*/
      DOPAR k=1, j
         S2: b(i,j,k) = a(i-1,j+i,k) + b(i,j-1,k)
      ENDDOPAR
   ENDDOSEQ

DOSEQ k = 1, n+1
   IF (k ≤ n) THEN /* scheduling (2i+1, 2k) for S1*/
      DOPAR j=k, n
         S1: a(i,j,k) = c(i,j,k-1) + 1
      ENDDOPAR
   IF (k ≥ 2) THEN /* scheduling (2i+1, 2k+3) for S3*/
      DOPAR j=k-1, n
         S3: c(i,j,k) = c(i,j,k-1) + b(i,j-1,k+i-1) + a(i,j-k+1,k)
      ENDDOPAR
   ENDDOSEQ
ENDDOSEQ

- Loop distribution of j, k loops: S2 then S1 + S3.
- Loop interchange of j and k loops for S1 and S3.
- Loop shifting in k, then loop distribution of j loop.
Allen-(Callahan)-Kennedy (1987): loop distribution

**AK(G, k):**
- Remove from G all edges of level < k.
- Compute $G_1, \ldots, G_s$ the s SCCs of G in topological order.
  - If $G_i$ has a single statement $S$, with no edge, generate DOPAR loops in all remaining dimensions, and generate code for $S$.
  - Otherwise:
    - Generate DOPAR loops from level $k$ to level $l - 1$, and a DOSEQ loop for level $l$, where $l$ is the minimal level in $G_i$.
    - call AK($G_i, l + 1$). /* $d_S$ sequential loops for statement $S$ */

Variant of (dual of) KMW with DOPAR as high as possible.
Allen-(Callahan)-Kennedy (1987): loop distribution

AK(G, k):
- Remove from G all edges of level < k.
- Compute \( G_1, \ldots, G_s \) the s SCCs of G in topological order.
  - If \( G_i \) has a single statement \( S \), with no edge, generate DOPAR loops in all remaining dimensions, and generate code for \( S \).
  - Otherwise:
    - Generate DOPAR loops from level \( k \) to level \( l - 1 \), and a DOSEQ loop for level \( l \), where \( l \) is the minimal level in \( G_i \).
    - call AK\((G_i, l + 1)\). /* \( d_S \) sequential loops for statement \( S \) */

Variant of (dual of) KMW with DOPAR as high as possible.

Theorem (Optimality for AK w.r.t. dependence levels)

Nested loops \( L \), RDG G with levels. One can build some nested loops \( L' \), with same structure as \( L \) and same RDG as G, with bounds parameterized by \( N \) such that, for each SCC \( G_i \) of G, there is a path in the EDG of \( L' \) that visits \( \Omega(N^{d_S}) \) times each statement \( S \) of \( G_i \) (\( d_S \): depth w.r.t. \( S \)).
Boolean $DV(G, k)$ /* $G$ uniformized graph, with virtual and actual nodes */

- Build $G'$ generated by the zero-weight multi-cycles of $G$.
- Modify slightly $G'$ (technical detail not explained here).
- Choose $\vec{X}$ (vector) and, for each $S$ in $G'$, $\rho_S$ (scalar) s.t.:

  \[
  \begin{cases}
  \text{if } e = (u, v) \in G' \text{ or } u \text{ is virtual}, & \vec{X}.\vec{w}(e) + \rho_v - \rho_u \geq 0 \\
  \text{if } e \notin G' \text{ and } u \text{ is actual}, & \vec{X}.\vec{w}(e) + \rho_v - \rho_u \geq 1
  \end{cases}
  \]

  For each actual node $S$ of $G$ let $\rho^k_S = \rho_S$ and $\vec{X}^k_S = \vec{X}$.

- Compute $G'_1, \ldots, G'_s$ the SCC of $G'$ with $\geq 1$ actual node:
  - If $G'$ is empty or has only virtual nodes, return TRUE.
  - If $G'$ is strongly connected with $\geq 1$ actual node, return FALSE.
  - Otherwise, return $\bigwedge_{i=1}^{s} DV(G'_i, k + 1)$ ($\bigwedge =$ logical AND).

Dual of KMW after dependence uniformization. Analyzing the cycle weights in $G'$ leads to a variant to get a max. number of permutable loops.
General affine multi-dimensional schedules (Feautrier)

Affine dependences (or even relations): $T(\vec{j})$ depends on $S(\vec{i})$ if $(\vec{i}, \vec{j}) \in \mathcal{D}_e$ where $e = (S, T)$ and $\mathcal{D}_e$ is a polyhedron.

- Look for affine schedule $\sigma$ such that $\sigma(S, \vec{i}) <_{\text{lex}} \sigma(T, \vec{j})$ for all $(\vec{i}, \vec{j}) \in \mathcal{D}_e$. Use affine form of Farkas lemma (mechanical operation).
- Write $\sigma(S, \vec{i}) + \epsilon_e \leq \sigma(T, \vec{j})$ with $\epsilon \geq 0$ and maximize the number of dependence edges $e$ such that $\epsilon_e \geq 1$.
- Remove edges $e$ such that $\epsilon_e \geq 1$ and continue to get remaining dimensions $\mathcal{G}$ multi-dimensional affine schedule.

Generalization of the constraints used in the dual of KMW.
Affine dependences (or even relations): $T(\vec{j})$ depends on $S(\vec{i})$ if $(\vec{i}, \vec{j}) \in D_e$ where $e = (S, T)$ and $D_e$ is a polyhedron.

- Look for affine schedule $\sigma$ such that $\sigma(S, \vec{i}) <_{\text{lex}} \sigma(T, \vec{j})$ for all $(\vec{i}, \vec{j}) \in D_e$. Use affine form of Farkas lemma (mechanical operation).
- Write $\sigma(S, \vec{i}) + \epsilon_e \leq \sigma(T, \vec{j})$ with $\epsilon_e \geq 0$ and maximize the number of dependence edges $e$ such that $\epsilon_e \geq 1$.
- Remove edges $e$ such that $\epsilon_e \geq 1$ and continue to get remaining dimensions \(\therefore\) multi-dimensional affine schedule.

Generalization of the constraints used in the dual of KMW.

To perform tiling, look for several dimensions (permutable loops) such that $\sigma(T, \vec{j}) - \sigma(S, \vec{i}) \geq 0$ instead of $\sigma(T, \vec{j}) - \sigma(S, \vec{i}) \geq 1$. But more complicated to avoid the $\vec{0}$ solution and guarantee linear independence. Key idea in Pluto: minimize dependence distance $\sigma(T, \vec{j}) - \sigma(S, \vec{i})$. 
Loop parallelization: optimality w.r.t. dep. abstraction

Allen-Kennedy (1987) loop distribution, optimal for levels.

Wolf-Lam (1991) unimodular, optimal for direction vectors and one statement. Based on finding permutable loops.

Feautrier (1992) general affine scheduling, complete for affine dependences and affine transformations, but not optimal. Relies on Farkas lemma.

Yet another application of SUREs: understand “iterations”

Fortran DO loops:

```fortran
DO i=1, N
    DO j=1, N
        a(i,j) = c(i,j-1)
        c(i,j) = a(i,j) + a(i-1,N)
    ENDDO
ENDDO
```

C for and while loops:

```c
y = 0; x = 0;
while (x <= N && y <= N) {
    if (?) {
        x=x+1;
        if (y >= 0 && ?) y=y-1;
    }
    y=y+1;
}
```

Uniform recurrence equations:

\[ \forall p \in \{p = (i, j) \mid 1 \leq i, j \leq N\} \]

\[
\begin{align*}
    a(i, j) &= c(i, j - 1) \\
    b(i, j) &= a(i - 1, j) + b(i, j + 1) \\
    c(i, j) &= a(i, j) + b(i, j)
\end{align*}
\]
KERNEL OFFLOADING AND LOOP TILING
Industrial tools: pretty good for optimizing computation kernel
But still a huge problem for feeding the accelerators with data.

Our idea (∼2009): use HLS tools as back-end compilers, assuming it puts
the necessary computing resources to be limited by bandwidth.

- Push all the dirty work in the back-end compiler.
- Optimize transfers at C level.
- Compile any new functions with the same HLS tool.
High-level synthesis (HLS) tools for FPGA

Industrial tools: pretty good for optimizing computation kernel
But still a huge problem for feeding the accelerators with data.

Our idea (~2009): use HLS tools as back-end compilers, assuming it puts the necessary computing resources to be limited by bandwidth.
- Push all the dirty work in the back-end compiler.
- Optimize transfers at C level.
- Compile any new functions with the same HLS tool.

Use Altera C2H as a back-end compiler. Main features:
- Syntax-directed translation to hardware:
  - Local array = local memory, other arrays/pointers = external memory.
  - Hierarchical FSMs: outer FSM stalls to wait for the latest inner FSM.
- Software pipelined loops:
  - Basic software pipelining with rough data dependence analysis.
  - Latency-aware pipelined DDR accesses (with internal FIFOs).
- Full interface within the complete system:
  - Accelerator(s) initiated as (blocking or not) function call(s).
  - Possibility to define FIFOs between accelerators.

Similar study Pouchet et al. FPGA’13 for Xilinx AutoESL
Throughput when accessing (asymmetric) DDR memory

Ex: DDR-400 128Mbx8, size 16MB, CAS 3, 200MHz. Successive reads, same row = 10 ns, different rows = 80 ns. Even if fully pipelined ($\lambda=1$), a bad spatial DDR locality can kill performances by a factor 8! Example:

```c
void vector_sum (int* __restrict__ a, b, c, int n) {
    for (int i = 0; i < n; i++) c[i] = a[i] + b[i];
}
```

C2H-compiled code: pipelined but time gaps & data thrown away.
Throughput when accessing (asymmetric) DDR memory

Ex: DDR-400 128Mx8, size 16MB, CAS 3, 200MHz. Successive reads, same row = 10 ns, different rows = 80 ns. Even if fully pipelined (λ=1), a bad spatial DDR locality can kill performances by a factor 8! Example:

```c
void vector_sum (int* __restrict__ a, b, c, int n) {
    for (int i = 0; i < n; i++) c[i] = a[i] + b[i];
}
```

Block version: reduces gaps, exploits bursts and temporal reuse.
Throughput when accessing (asymmetric) DDR memory

Ex: DDR-400 128Mbx8, size 16MB, CAS 3, 200MHz. Successive reads, same row = 10 ns, different rows = 80 ns. Even if fully pipelined (\(\lambda=1\)), a bad spatial DDR locality can kill performances by a factor 8! Example:

```c
void vector_sum (int* __restrict__ a, b, c, int n) {
    for (int i = 0; i < n; i++) c[i] = a[i] + b[i];
}
```

Block version: reduces gaps, exploits bursts and temporal reuse.

Typical figure with speed-up vs block size (here vector sum).
Strip-mining and loop distribution?

Loop distribution: too large local memory.  
Unrolling: too many registers.  
\[ \text{strip-mining + loop distribution.} \]

```c
for (i=0; i<MAX; i=i+BLOCK) {
    for (j=0; j<BLOCK; j++) a_tmp[j] = a[i+j]; //prefetch
    for (j=0; j<BLOCK; j++) b_tmp[j] = b[i+j]; //prefetch
    for (j=0; j<BLOCK; j++) c_tmp[i+j] = a_tmp[j] + b_tmp[j];
    for (j=0; j<BLOCK; j++) c[i+j] = c_tmp[i+j]; //store
}
```

Does not work!

First data received latency first request DDR i loop time pipeline computation j loop fetch a,b j loops store j loop

Accesses to arrays a and b still interleaved!

Loop latency penalty.

Outer loop not pipelined.
Strip-mining and loop distribution?

Loop distribution: too large local memory. Unrolling: too many registers. \[ \text{strip-mining + loop distribution.} \]

```c
for (i=0; i<MAX; i=i+BLOCK) {
    for (j=0; j<BLOCK; j++) a_tmp[j] = a[i+j]; //prefetch
    for (j=0; j<BLOCK; j++) b_tmp[j] = b[i+j]; //prefetch
    for (j=0; j<BLOCK; j++) c_tmp[i+j] = a_tmp[j] + b_tmp[j];
    for (j=0; j<BLOCK; j++) c[i+j] = c_tmp[i+j]; //store
}
```

Does not work!

- Accesses to arrays a and b still interleaved!
- Loop latency penalty.
- Outer loop not pipelined.
Introduce false dependences?

```c
for (i=0; i<MAX; i=i+BLOCK) {
    for (j=0; j<BLOCK; j++) tmp = BLOCK; a_tmp[j] = a[i+j];
    for (j=0; j<tmp; j++) b_tmp[j] = b[i+j];
    for (j=0; j<BLOCK; j++) c_tmp[i+j] = a_tmp[j] + b_tmp[j];
    for (j=0; j<BLOCK; j++) c[i+j] = c_tmp[i+j];
}
```

Still pay loop latency penalty and poor outermost loop pipeline.
Emulating (linearizing) nested loops?

i=0; j=0; bi=0;
for (k=0; k<4*MAX; k++) {
    if (j==0) a_tmp[i] = a[bi+i];
    else if (j==1)
        b_tmp[i] = b[bi+i];
    else if (j==2)
        c_tmp[i] = a_tmp[i] + b_tmp[i];
    else c[bi+i] = c_tmp[i];

    if (i<BLOCK-1) i++;
    else {
        i=0;
        if (j<3) j++;
        else {j=0; bi = bi + BLOCK;}
    }
}

- Need to use restrict pragma for all arrays.
- $\lambda = 21!$ Problem with dependence analyzer and software pipeliner.
- Better behavior ($\lambda = 3$) with case statement: by luck.
- Further loop unrolling to get $\lambda = 1$: too complex.
- But still a problem with interleaved DDR accesses due to speculative prefetching!
Emulating nested loops with a single transfer instruction?

```c
i=0; j=0; bi=0;
for (k=0; k<3*MAX; k++) {
    if (j==0) { ptr_1 = &a[bi+i]; ptr_2 = &a_tmp[i]; }
    else if (j==1) { ptr_1 = &b[bi+i]; ptr_2 = &b_tmp[i]; }
    else if (j==2) { ptr_1 = &c_tmp[i]; ptr_2 = &c[bi+i];
        c_tmp[i] = a_tmp[i] + b_tmp[i]; }
    *ptr_2 = *ptr_1;
    if (i<BLOCK-1) i++;
    else { i=0; if (j<2) j++; else {j=0; bi = bi + BLOCK;}}
}
```

- No more interleaving between arrays a and b;
- $\lambda$ not equal to 1, unless restrict pragma added: but leads to potentially wrong codes (data dependences are lost).

How to decrease $\lambda$ and generalize to more complex codes?

Communicating C processes, with suitable synchronizations.
Source-to-source transformations and kernel acceleration

How to optimize transfers automatically?

- C-code → HLS tool → VHDL code → FPGA board

\[
\begin{align*}
\text{for } (i=0, i<=2n-1; i++) \\
c[i] &= 0; \\
\text{for } (i=0; i<n; i++) \\
\quad \text{for } (j=0; j<n; j++) \\
\qquad &c[i+j] = c[i+j] + A[i]*B[j];
\end{align*}
\]

Order: lexico along \((i + j, j)\).
Product of two polynomials:
- arguments in $A$ and $B$;
- result in $C$.
- dep. distance $(1, -1)$.
- now $(1, 1)$.

```c
for (i=0, i<=2n-1; i++)
    c[i] = 0;
for (i=0; i<n; i++)
    for (j=0; j<n; j++)
        c[i+j] = c[i+j] + A[i]*B[j];
```

Order: lexico along $(n - j - 1, i)$. 

---

**Loop tiling and permutable loops**
Loop tiling and permutable loops

Product of two polynomials:
- arguments in $A$ and $B$;
- result in $C$.
- dep. distance $(1, -1)$.
  - now $(1, 1), (1, 0), (0, 1)$.

```c
for (i=0, i<=2n-1; i++)
c[i] = 0;
for (i=0; i<n; i++)
  for (j=0; j<n; j++)
    c[i+j] = c[i+j] + A[i]*B[j];
```

Order: lexico along $(n - j - 1, i)$.
Tiling: $(\left\lfloor \frac{n-j-1}{s_1} \right\rfloor, \left\lfloor \frac{i}{s_2} \right\rfloor, n - j - 1, i)$. 
Loop tiling and permutable loops

Product of two polynomials:
- arguments in $A$ and $B$;
- result in $C$.
- dep. distance $(1, -1)$.
  - now $(0, 1)$.

```
for (i=0, i<=2n-1; i++)
c[i] = 0;
for (i=0; i<n; i++)
  for (j=0; j<n; j++)
    c[i+j] = c[i+j] + A[i]*B[j];
```

Order: lexico along $(i + j, j)$.
Loop tiling and permutable loops

Product of two polynomials:
- arguments in $A$ and $B$;
- result in $C$.
- dep. distance $(1, -1)$.

Now $(0, 1)$.

```c
for (i=0, i<=2n-1; i++)
c[i] = 0;
for (i=0; i<n; i++)
 for (j=0; j<n; j++)
    c[i+j] = c[i+j] + A[i]*B[j];
```

Order: lexico along $(i+j, j)$.
Tiling: $\left(\left\lfloor \frac{i+j}{s_1} \right\rfloor, \left\lfloor \frac{i}{s_2} \right\rfloor, i+j, i\right)$. 
Validity of loop tiling through permutability

Permutability condition:

- Dependences not loop-carried are not relevant. Indeed, \((\vec{0}, \vec{d})\) remains unchanged, thus lexicopositive.
Validity of loop tiling through permutability

Permutability condition:

- Dependences not loop-carried are not relevant. Indeed, \((\vec{0}, \vec{d})\) remains unchanged, thus lexicopositive.
- \(\vec{d} \geq \vec{0}\) for all distance vector \(\vec{d}\): \(\vec{d} > \vec{0} \Rightarrow P\vec{d} > \vec{0}\) (\(P\) permutation).
Validity of loop tiling through permutability

Permutability condition:

- Dependences not loop-carried are not relevant. Indeed, \((\vec{0}, \vec{d})\) remains unchanged, thus lexicopositive.
- \(\vec{d} \geq \vec{0}\) for all distance vector \(\vec{d}\): \(\vec{d} \succ \vec{0} \Rightarrow P\vec{d} \succ \vec{0}\) (\(P\) permutation).

Tiling validity: After tiling, \(\vec{i} \mapsto (\vec{l}, \vec{ii}) = ([\vec{i}/\vec{s}], \vec{i} \mod \vec{s})\). Furthermore:

\[ j \geq i \Rightarrow j - i \geq 0 \Rightarrow (j - i)/\vec{s} \geq \vec{0} \Rightarrow j/\vec{s} \geq i/\vec{s} \Rightarrow [j/\vec{s}] \geq [i/\vec{s}] \]

Dep. \(\vec{d} \succ \vec{0}\) becomes \(\vec{d}' \succeq \vec{0}\). Tiles can still be scheduled.

Valid: yes
Validity of loop tiling through permutability

Permutability condition:

- Dependences not loop-carried are not relevant. Indeed, \((\vec{0}, \vec{d})\) remains unchanged, thus lexicopositive.
- \(\vec{d} \geq \vec{0}\) for all distance vector \(\vec{d}\): \(\vec{d} \succ \vec{0} \Rightarrow P\vec{d} \succ \vec{0}\) (\(P\) permutation).

Tiling validity: After tiling, \(\vec{i} \mapsto (\vec{l}, \vec{i}) = ([\vec{i}/\vec{s}], \vec{i} \mod \vec{s})\). Furthermore:

\[
\vec{j} \geq \vec{i} \Rightarrow \vec{j} - \vec{i} \geq \vec{0} \Rightarrow (\vec{j} - \vec{i})/\vec{s} \geq \vec{0} \Rightarrow \vec{j}/\vec{s} \geq \vec{i}/\vec{s} \Rightarrow \lfloor \vec{j}/\vec{s} \rfloor \geq \lfloor \vec{i}/\vec{s} \rfloor
\]

Dep. \(\vec{d} \succ \vec{0}\) becomes \(\vec{d}' \succeq \vec{0}\). Tiles can still be scheduled.
Validity of loop tiling through permutability

Permutability condition:

- Dependences not loop-carried are not relevant. Indeed, $(\vec{0}, \vec{d})$ remains unchanged, thus lexicopositive.
- $\vec{d} \geq \vec{0}$ for all distance vector $\vec{d}$: $\vec{d} \succ \vec{0} \Rightarrow P\vec{d} \succ \vec{0}$ ($P$ permutation).

Tiling validity: After tiling, $i \mapsto (\vec{l}, \vec{ii}) = ([i/\vec{s}], i \mod \vec{s})$. Furthermore:

$$j \geq i \Rightarrow j - i \geq 0 \Rightarrow (j - i)/\vec{s} \geq 0 \Rightarrow j/\vec{s} \geq i/\vec{s} \Rightarrow [j/\vec{s}] \geq [i/\vec{s}]$$

$\Rightarrow$ Dep. $\vec{d} \succ \vec{0}$ becomes $\vec{d}' \succeq \vec{0}$. Tiles can still be scheduled.

Tile shape given by tile edges. Ex: \( P = \begin{pmatrix} 2 & 1 \\ 0 & 3 \end{pmatrix} \). \( H = P^{-1} \)

\[
H = \frac{1}{6} \begin{pmatrix} 3 & -1 \\ 0 & 2 \end{pmatrix}.
\]

With \( D = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \]

\[
HD = \frac{1}{6} \begin{pmatrix} 3 & 2 \\ 0 & 2 \end{pmatrix} \geq \bar{0}.
\]

Tile computation volume equal to \( |\det P| = 1/|\det H| \).
“Ratio” of computation and communication volume

Tile shape given by tile edges. Ex: \( P = \begin{pmatrix} 2 & 1 \\ 0 & 3 \end{pmatrix} \). \( H = P^{-1} \)

\( H = \frac{1}{6} \begin{pmatrix} 3 & -1 \\ 0 & 2 \end{pmatrix} \). With \( D = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \), \( HD = \frac{1}{6} \begin{pmatrix} 3 & 2 \\ 0 & 2 \end{pmatrix} \). With \( HD \geq 0 \).

Tile computation volume equal to \( |\det P| = 1/|\det H| \).

Tile communication volume roughly \( \frac{\sum_{i=1}^{n} \sum_{j=1}^{m} (HD)_{i,j}}{|\det H|} \). Indeed:

\[ |\det(d, p_2, \ldots, p_n)| = |(p_2 \wedge \cdots \wedge p_n).d| = |(\det P)h_1.d| = |\det P|(h_1.d) \]
"Ratio" of computation and communication volume

Tile shape given by tile edges. Ex: \( P = \begin{pmatrix} 2 & 1 \\ 0 & 3 \end{pmatrix} \). \( H = P^{-1} \)

\[
H = \frac{1}{6} \begin{pmatrix} 3 & -1 \\ 0 & 2 \end{pmatrix}.
\]

With \( D = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \), \( HD = \frac{1}{6} \begin{pmatrix} 3 & 2 \\ 0 & 2 \end{pmatrix} \geq 0. \)

Tile computation volume equal to \( |\det P| = 1/|\det H| \).

Tile communication volume roughly \( \sum_{i=1}^{n} \sum_{j=1}^{m} (HD)_{i,j} / |\det H| \). Indeed:

\[
|\det(d, p_2, \ldots, p_n)| = |(p_2 \land \cdots \land p_n).d| = |(\det P)h_1.d| = |\det P|(h_1.d)
\]

Aspect ratio Minimize communication for a given computation volume.

Minimize \( \sum_{i=1}^{n} \sum_{j=1}^{m} (HD)_{i,j} / |\det H|^{1/n} \) subject to \( \det H \neq 0, \ HD \geq 0. \)
“Ratio” of computation and communication volume

Tile shape given by tile edges. Ex: \( P = \begin{pmatrix} 2 & 1 \\ 0 & 3 \end{pmatrix} \). \( H = P^{-1} \)

\[
H = \frac{1}{6} \begin{pmatrix} 3 & -1 \\ 0 & 2 \end{pmatrix} .
\]
With \( D = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \), \( HD = \frac{1}{6} \begin{pmatrix} 3 & 2 \\ 0 & 2 \end{pmatrix} \geq 0 \).

Tile computation volume equal to \( | \det P | = 1 / | \det H | \).

Tile communication volume roughly \( \frac{\sum_{i=1}^{n} \sum_{j=1}^{m} (HD)_{i,j}}{| \det H |} \). Indeed:

\[
| \det(d, p_2, \ldots, p_n) | = | (p_2 \wedge \cdots \wedge p_n).d | = | (\det P) h_1.d | = | \det P | (h_1.d)
\]

Aspect ratio Minimize communication for a given computation volume.

Minimize \( \frac{\sum_{i=1}^{n} \sum_{j=1}^{m} (HD)_{i,j}}{| \det H |^{\frac{1}{n}}} \) subject to \( \det H \neq 0, \ HD \geq 0 \). Solvable!

- If \( D \) is square, non singular, opt. for \( H = D^{-1} \) and ratio \( n | \det D |^{\frac{1}{n}} \).
- General case: cone \( C(D) \), opt. for \( n \) generators of \( C^*(D) \), scaled to induce the same communication on all faces.
Generating loop bounds for tiled codes

- “Scanning Polyhedra with DO Loops”, Ancourt, Irigoin, PPoPP’91.
- “Parameterized Tiled Loops for Free”, Renga., Kim, Rajopadhye, Strout, PLDI’07.

Tile of size \( \vec{s} \) with origin \( \vec{i}_0 \): \( \{ \vec{i} \mid \vec{i}_0 \leq \vec{i} \leq \vec{i}_0 + \vec{s} - 1 \} \).

**Elementary bounding box method**: many empty tiles.

```plaintext
// Original code
for(t=1; t<=M; t++)
  for(i=2; i<=N; i++)
    S(t,i);

// Skewed code
for(t=1; t<=M; t++)
  for(k=2+t; k<=N+t; k++)
    S(t,k-t);

// Tiled code, many empty iterations
for(T=1; T<=M; T+=st)
  for(K=3; K<=N+M; K+=sk)
    for(t=max(T,1); t<=min(T+st-1,M); t++)
      for(k=max(K,2+t); k<=min(K+sk-1,N+t); k++)
        S(t,k-t);
```

//Original code
for(t=1; t<=M; t++)
  for(i=2; i<=N; i++)
    S(t,i);

//Skewed code
for(t=1; t<=M; t++)
  for(k=2+t; k<=N+t; k++)
    S(t,k-t);

//Tiled code, many empty iterations
for(T=1; T<=M; T+=st)
  for(K=3; K<=N+M; K+=sk)
    for(t=max(T,1); t<=min(T+st-1,M); t++)
      for(k=max(K,2+t); k<=min(K+sk-1,N+t); k++)
        S(t,k-t);
Generating loop bounds for tiled codes

- “Scanning Polyhedra with DO Loops”, Ancourt, Irigoin, PPoPP’91.
- “Parameterized Tiled Loops for Free”, Renga., Kim, Rajopadhye, Strout, PLDI’07.

Tile of size \( \vec{s} \) with origin \( \vec{i}_0 \): \( \{ \vec{i} | \vec{i}_0 \leq \vec{i} \leq \vec{i}_0 + \vec{s} - 1 \} \).

Exact computation of non-empty tiles for fixed tile sizes.

//Original code
for(t=1; t<=M; t++)
    for(i=2; i<=N; i++)
        S(t,i);

//Skewed code
for(t=1; t<=M; t++)
    for(k=2+t; k<=N+t; k++)
        S(t,k-t);

Code not depicted. Only for fixed tile sizes. Express the lattice \( \mathcal{L}(\vec{s}) \) of all tile origins \( \vec{i}_0 = \vec{0} \mod \vec{s} \), and project existential variables.
Generating loop bounds for tiled codes

- “Scanning Polyhedra with DO Loops”, Ancourt, Irigoin, PPoPP’91.
- “Parameterized Tiled Loops for Free”, Renga., Kim, Rajopadhye, Strout, PLDI’07.

Tile of size $\vec{s}$ with origin $\vec{i}_0$: \( \{ \vec{i} \mid \vec{i}_0 \leq \vec{i} \leq \vec{i}_0 + \vec{s} - 1 \} \).

Approx. iterations \( \{ \vec{z} \mid Q\vec{z} \geq \vec{b} \} \) by the “outer set” \( \{ \vec{z} \mid Q\vec{z} + Q^+\vec{s} \geq \vec{b} \} \).

//Skewed code
for (t=1; t<=M; t++)
  for (k=2+t; k<=N+t; k++)
    S(t,k-t);

Outer set shift:
- \( 1 \leq t \leq M \Rightarrow 2 - st \leq t \leq M \)
- \( 2 \leq k - t \leq N \Rightarrow 3 - sk \leq k - t \leq N + st - 1 \)

//Tiled code, fewer empty iterations
LBT = 2-st; LBT = ceil(LBT/st)*st;
for (T=LBT; T<=M; T+=st) {
  LBK = 3+t-sk; LBK = ceil(LBK/sk)*sk;
  for (K=LBK; K<=N+t+st-1; K+=sk)
    for (t=max(T,1); t<=min(T+st-1,M); t++)
      for (k=max(K,2+t); k<=min(K+sk-1,N+t); k++)
        S(t,k-t);
}
INTER-TILE DATA REUSE AND LOCAL STORAGE
General specification of data transfers

Definition

- **Load**($T$): data loaded from DDR just before executing tile $T$.
- **Store**($T$): data stored to DDR just after $T$.
- **In**($T$): input data for $T$, i.e., read before being possibly written in $T$.
- **Out**($T$): output data for $T$, i.e., data written in $T$.

Minimal dependence structure

Goals

- Reuse local data: intra- and inter-tile reuse in a tile strip.
- Do not store back after each write: external memory not up-to-date.
- Minimize live-ranges in local memory: need local memory allocation.
Inter-tile data reuse
Inter-tile data reuse

Global

Local

Load

Store

Load

Store

Comp

Comp
Inter-tile data reuse
Inter-tile data reuse enables pipelining
Inter-tile reuse formula w.r.t. a generic tile $T$

\[
\text{Load}(T) = \text{In}(T) \setminus \bigcup_{T' \sqsubset_s T} \text{In}(T') \cup \text{Out}(T')
\]

\[
\begin{align*}
&\left\{ \begin{array}{l}
    s_i l \leq i < s_i (l + 1) \\
    s_j J \leq j < s_j (J + 1) \\
    i, j \in \text{Domain}
\end{array} \right.
\end{align*}
\]

Quadratic if $T$ indexed by $\left\lfloor \vec{i}/\vec{s} \right\rfloor$. 
Load($T$) = $\text{In}(T) \setminus \bigcup_{T' \subseteq sT} \text{In}(T') \cup \text{Out}(T')$

\[
\begin{align*}
I & \leq i < I + s_i \\
J & \leq j < J + s_j \\
i, j & \in \text{Domain}
\end{align*}
\]

Affine with tile origin? Not yet.

\[
\begin{align*}
I & \equiv 0 \pmod{s_i} \\
J & \equiv 0 \pmod{s_j}
\end{align*}
\]
Inter-tile reuse formula w.r.t. a generic tile $T$

\[
\text{Load}(T) = \text{In}(T) \setminus \bigcup_{T' \sqsubseteq_s T} \text{In}(T') \cup \text{Out}(T')
\]

Still not affine
Inter-tile reuse formula w.r.t. a generic tile $T$

$$\text{Load}(T) = \text{In}(T) \setminus \bigcup_{T' \subseteq s T} \bigcup_{x \in T'} \text{in}(x) \cup \text{out}(x)$$

Piece-wise affine!
Inter-tile reuse formula w.r.t. a generic tile $T$

$$\text{Load}(T) = \text{In}(T) \setminus \bigcup_{T' \prec_s T} \text{In}(T') \cup \text{Out}(T')$$

Still piece-wise affine.
Computations can be done with iscc.
Approximations: why?

Some operations *may* execute
- if conditions that are not analyzable.

Some data *may* be accessed
- access functions that are not fully analyzable.

Approximated In/Out sets for tiles  📈 $\overline{\text{In}}, \overline{\text{Out}}, \overline{\text{Out}}$.
- due to the analysis (e.g., array regions);
- by choice to represent simpler sets (e.g., hyper-rectangles);
- to simplify the analysis (e.g., Fourier-Motzkin).

Approximated Load/Store sets  📈 $\overline{\text{Store}}, \overline{\text{Load}}$.
- to simplify code generation;
- to perform communications by blocks;
- to simplify memory allocation;
- ...
May-write approximation hazard

Problem:

- Tile $T$ may write $X$, i.e., $X \in \overline{\text{Out}}(T)$
- Tile $T'$ may read $X$, i.e., $X \in \overline{\text{In}}(T')$
- Only $T$ and $T'$ may access $X$

Should we load $X$? When?
May-write approximation hazard

Problem:
- Tile T may write X, i.e., \( X \in \overline{\text{Out}}(T) \)
- Tile T’ may read X, i.e., \( X \in \overline{\text{In}}(T’) \)
- Only T and T’ may access X

Should we load X? When?
- T’ happens before T 🔄 load before T’
- T’ happens after T and \( X \in \overline{\text{Out}}(T) \) 🔄 do not load
- T’ happens after T and \( X \notin \overline{\text{Out}}(T) \) 🔄 load before T
Reuse formula with approximation and \textit{point-wise} functions

\[ \text{Load}(T) = F(T) \setminus \bigcup_{T' \subseteq s T} F(T') \]

\( F \) defined at tile level.

Can we use the same trick as for the exact case?
Reuse formula with approximation and \textit{point-wise} functions

\[
\text{Load}(T) = F(T) \setminus \bigcup_{T' \prec_s T} F(T')
\]

Yes if

\[
\bigcup_{T' \sqsubseteq_s T} F(T') = \bigcup_{T' \prec_s T} F(T')
\]
Reuse formula with approximation and \textit{point-wise} functions

\[
\text{Load}(T) = F(T) \setminus \bigcup_{T' \prec s T} F(T')
\]

\(\mathcal{C}\) set of all tiles, \(\mathcal{C}_1, \mathcal{C}_2 \subseteq \mathcal{C}\) such that \(\bigcup_{T \in \mathcal{C}_1} T = \bigcup_{T \in \mathcal{C}_2} T\)

\[
\bigcup_{T \in \mathcal{C}_1} F(T) = \bigcup_{T \in \mathcal{C}_2} F(T)
\]
Reuse formula with approximation and \textit{point-wise} functions

\[ \text{Load}(T) = F(T) \setminus \bigcup_{T' \prec_s T} F(T') \]

\( C \) set of all tiles, \( C_1, C_2 \subseteq C \) such that \( \bigcup_{T \in C_1} T = \bigcup_{T \in C_2} T \)

\[ \bigcup_{T \in C_1} F(T) \overset{?}{=} \bigcup_{T \in C_2} F(T) \]

Iff \( F \) is \textit{point-wise}:

\[ \exists f, \forall T \in C, F(T) = \bigcup_{x \in T} f(x) \]

\( \therefore \) similar to the exact case.

Instance-wise order for sequential and parallel loops

```c
for(i=0; i<n; i++) {
    for(j=0; j<n; j++) {
        S: ...
        T: ...
    }
}
```

- Total order $\prec$ defined by a sequential schedule $\sigma$ and lexicographic order.
- $\sigma(S(i, j)) = (i, j, 0)$, $\sigma(T(i, j)) = (i, j, 1)$.
- $O \prec O'$ iff $\sigma(O) \prec_\text{lex} \sigma(O')$.
- $S(i, j) \prec T(i', j')$ iff $i < i'$ or $(i = i'$ and $j \leq j')$. 
Instance-wise order for sequential and parallel loops

```c
for(i=0; i<n; i++) {
    for(j=0; j<n; j++) {
        S: ...  
        T: ...  
    }
}
```

- **Total order** $\prec$ defined by a sequential schedule $\sigma$ and lexicographic order.
  
  $\sigma(S(i,j)) = (i,j,0)$, $\sigma(T(i,j)) = (i,j,1)$.

- $O \prec O'$ iff $\sigma(O) <_{\text{lex}} \sigma(O')$.

- $S(i,j) \prec T(i',j')$ iff $i < i'$ or $(i = i'$ and $j \leq j'$).

```c
for(i=0; i<n; i++) {
    forpar(j=0; j<n; j++) {
        S: ...  
        T: ...  
    }
}
```

- Partial order $\prec$, some form of lexicographic order.

- $S(i,j) \prec T(i',j')$ iff $i < i'$ or $(i = i'$ and $j = j'$).
Instance-wise order for sequential and parallel loops

\[ \text{for}(i=0; i<n; i++) \{ \]
  \[ \text{for}(j=0; j<n; j++) \{ \]
    S: \ldots
    T: \ldots
  \}
\]

- Total order \( < \) defined by a sequential schedule \( \sigma \) and lexicographic order.
  \[ \sigma(S(i,j)) = (i, j, 0), \sigma(T(i,j)) = (i, j, 1). \]
  \[ O < O' \text{ iff } \sigma(O) <_{\text{lex}} \sigma(O'). \]
  \[ S(i,j) < T(i',j') \text{ iff } i < i' \text{ or } (i = i' \text{ and } j \leq j'). \]

\[ \text{for}(i=0; i<n; i++) \{ \]

More general orders: polyhedral fragment of X10

**X10 language** developed at IBM, variant at Rice (V. Sarkar)
- PGAS (partitioned global address space) memory principle.
- Parallelism of threads: in particular keywords *finish*, *async*, *clock*.
- No deadlocks by construction but non-determinism.

**Polyhedral X10** Yuki, Feautrier, Rajopadhye, Saraswat (PPoPP 2013)
Can we analyze the code for data races?

```plaintext
finish {
    for(i in 0..n-1) {
        S1;
        async {
            S2;
        }
    }
}

clocked finish {
    for(i in 0..n-1) {
        S1; advance();
        clocked async {
            S2; advance();
        }
    }
}
```

Can we analyze the code for data races? Yes. Similar to data-flow analysis. Partial order ≺: incomplete lexicographic order.

```
clocked finish {
    for(i in 0..n-1) {
        S1; advance();
        clocked async {
            S2; advance();
        }
    }
}
```

Undecidable. Partial order ≺ defined by ⃗x≺⃗y iff ⃗x≺⃗y or φ(⃗x) < φ(⃗y).

φ(⃗x) = # advances before (≺) ⃗x.
**More general orders: polyhedral fragment of X10**

        }
    }
}
```

**Yes.** Similar to data-flow analysis. Partial order `≺`: incomplete lexicographic order.

**Undecidable.** Partial order `≺_c` defined by \( \vec{x} ≺_c \vec{y} \) iff \( \vec{x} ≺ \vec{y} \) or \( \phi(\vec{x}) < \phi(\vec{y}) \).

\( \phi(\vec{x}) = \# \text{ advances before (for} ≺ \vec{x}.\)
Uses of liveness analysis:

- Necessary for memory reuse:
  - Register allocation: interference graph.
  - Array contraction: conflicting relations.
  - Even wire usage: bitwidth analysis.

- Important information for:
  - Communication: live-in/live-out sets (inlining, offloading)
  - Memory footprint (e.g., for cache prediction)
  - Lower/upper bounds on memory usage.
Liveness analysis

Uses of liveness analysis:

- Necessary for memory reuse:
  - Register allocation: interference graph.
  - Array contraction: conflicting relations.
  - Even wire usage: bitwidth analysis.

- Important information for:
  - Communication: live-in/live-out sets (inlining, offloading)
  - Memory footprint (e.g., for cache prediction)
  - Lower/upper bounds on memory usage.

Several variants:

- Value-based or memory-based analysis.
- Liveness sets or interference graphs.
- Control flow graphs (CFG): basic blocks, SSA, SSI, etc.
- Task graphs, parallel specifications: not really explored so far.
Array contraction: symbolic unrolling, analysis, mapping

\[ x = \ldots; \]
\[ y = x + \ldots; \]
\[ \ldots = y; \]
\[ \Rightarrow \]
\[ x = \ldots; \]
\[ x = x + \ldots; \]
\[ \ldots = x; \]
Array contraction: symbolic unrolling, analysis, mapping

\{(-1,i_1) \mid i_1 \geq 0, n \geq 3, i_1 \leq -1 + n\}
\]
Generalizations? Liveness sets not the right concept

**Inner parallelism**  Almost the same.
Generalizations? Liveness sets not the right concept

Inner parallelism  Almost the same.
Seq/Par nested loops  Can use a careful hierarchical approach.
Generalizations? Liveness sets not the right concept

**Inner parallelism**  Almost the same.

**Seq/Par nested loops**  Can use a careful hierarchical approach.

**Software pipelining**  Harder to get a concept of “time”.

---

On the right, values computed in $S(i - 1)$ and $L(i + 1)$ both conflict with those in $(C, i)$, but not with each other. **Not a clique.**
Reasoning at the level of traces

Define:

- \( a \in t \) iff \( a \) is executed in a trace \( t \);
- \( a \prec_t b \) iff \( a \in t \), \( b \in t \) and \( a \) is executed before \( b \) in \( t \);
- \( S_\exists(a, b) \) iff there is a trace \( t \) such that \( a \prec_t b \).
- \( R_\forall(a, b) = \neg S_\exists(b, a) \) iff, for all traces \( t \), \( a, b \in t \) implies \( a \prec_t b \).

Then, \( a \) and \( b \) conflict \(( a \bowtie b )\) if, for some trace \( t \), \( W_a \prec_t W_b \prec_t R_a \).
Reasoning at the level of traces

Define:

- $a \in t$ iff $a$ is executed in a trace $t$;
- $a \prec_t b$ iff $a \in t$, $b \in t$ and $a$ is executed before $b$ in $t$;
- $S \exists (a, b)$ iff there is a trace $t$ such that $a \prec_t b$.
- $R \forall (a, b) = \neg S \exists (b, a)$ iff, for all traces $t$, $a, b \in t$ implies $a \prec_t b$.

Then, $a$ and $b$ conflict ($a \bowtie b$) if, for some trace $t$, $W_a \prec_t W_b \prec_t R_a$.

Conservative approximations for $a \bowtie b$:

- iff $S \exists (W_a, R_a)$, $S \exists (W_a, W_b)$, $S \exists (W_b, R_a)$ iff
  $\neg R \forall (R_a, W_a)$, $\neg R \forall (W_b, W_a)$, $\neg R \forall (R_a, W_b)$.
- with an under-approximation $R \forall \subseteq R \forall$. 
Reasoning at the level of traces

Define:
- \( a \in t \) iff \( a \) is executed in a trace \( t \);
- \( a \prec_t b \) iff \( a \in t, b \in t \) and \( a \) is executed before \( b \) in \( t \);
- \( S_\exists(a, b) \) iff there is a trace \( t \) such that \( a \prec_t b \).
- \( R_\forall(a, b) = \neg S_\exists(b, a) \) iff, for all traces \( t \), \( a, b \in t \) implies \( a \prec_t b \).

Then, \( a \) and \( b \) conflict (\( a \Join b \)) if, for some trace \( t \), \( W_a \prec_t W_b \prec_t R_a \).

Conservative approximations for \( a \Join b \):
- \( \text{iff } S_\exists(W_a, R_a), S_\exists(W_a, W_b), S_\exists(W_b, R_a) \) iff 
  \( \neg R_\forall(R_a, W_a), \neg R_\forall(W_b, W_a), \neg R_\forall(R_a, W_b) \).
- with an under-approximation \( R_\forall \subseteq R_\forall \).

When \( R_\forall \) is a partial order \( \preceq \), \( a \Join b \) iff \( R_a \not\prec W_a, W_b \not\prec W_a, R_a \not\prec W_b \).

Covers sequential code, OpenMP-like loop parallelism, OpenMP-4.0 task parallelism, X10, OpenStream, even some form of if conditions, etc.
Modular mappings and lattices

Modulo mapping \( \vec{i} \mapsto \sigma(i) = M\vec{i} \mod \vec{b} \) (modulo componentwise).

Validity iff \( \vec{i} \not\propto \vec{j}, \vec{i} \neq \vec{j} \Rightarrow \sigma(i) \neq \sigma(j) \) iff, with \( DS = \{ \vec{i} - \vec{j} \mid \vec{i} \not\propto \vec{j} \} \),
\( DS \cap \ker \sigma = \{ \vec{0} \} \).

Lattice An allocation is optimal iff its kernel is a strictly admissible (integer) lattice for \( DS \) of minimal determinant (critical lattice).

- Successive modulo approach.
- Exhaustive search possible.
- Upper/lower bounds linked to Minkowski’s theorems, basis reduction, gauge functions.
  - good order of magnitude if \( DS \) is a polyhedron.
Modular mappings and lattices

Modulo mapping \( \vec{i} \mapsto \sigma(\vec{i}) = M\vec{i} \mod \vec{b} \) (modulo componentwise).

Validity iff \( i \nparallel j, \vec{i} \neq \vec{j} \Rightarrow \sigma(\vec{i}) \neq \sigma(\vec{j}) \) iff, with \( DS = \{ \vec{i} - \vec{j} \mid i \nparallel j \} \), \( DS \cap \ker \sigma = \{ \vec{0} \} \).

Lattice An allocation is optimal iff its kernel is a strictly admissible (integer) lattice for \( DS \) of minimal determinant (critical lattice).

0–Symmetric Polytope: vertices (8,1), (−8,−1), (−1,5), and (1,−5)

- Successive modulo approach.
- Exhaustive search possible.
- Upper/lower bounds linked to Minkowski’s theorems, basis reduction, gauge functions.
- Good order of magnitude if \( DS \) is a polyhedron.
Modular mappings and lattices

Modulo mapping \( \vec{i} \mapsto \sigma(\vec{i}) = M\vec{i} \mod \vec{b} \) (modulo componentwise).

Validity iff \( \vec{i} \not\propto \vec{j}, \vec{i} \neq \vec{j} \Rightarrow \sigma(\vec{i}) \neq \sigma(\vec{j}) \) iff, with \( DS = \{ \vec{i} - \vec{j} \mid \vec{i} \not\propto \vec{j} \} \), \( DS \cap \ker \sigma = \{ \vec{0} \} \).

Lattice An allocation is optimal iff its kernel is a \textit{strictly admissible} (integer) \textbf{lattice} for \( DS \) of minimal determinant (\textit{critical} lattice).

![Lattice diagram](image)

- Successive modulo approach.
- Exhaustive search possible.
- Upper/lower bounds linked to Minkowski’s theorems, basis reduction, gauge functions.
  - good order of magnitude if \( DS \) is a polyhedron.

Validity iff \( \vec{i} \ncong \vec{j}, \vec{i} \neq \vec{j} \Rightarrow \sigma(\vec{i}) \neq \sigma(\vec{j}) \) iff, with \( \text{DS} = \{ \vec{i} - \vec{j} \mid \vec{i} \ncong \vec{j} \} \), \( \text{DS} \cap \ker \sigma = \{ \vec{0} \} \).

Lattice An allocation is optimal iff its kernel is a strictly admissible (integer) lattice for DS of minimal determinant (critical lattice).

Lattice: Basis (7,0), (4,4) (i−j mod 7, j mod 4) Determinant: 28

- Successive modulo approach.
- Exhaustive search possible.
- Upper/lower bounds linked to Minkowski’s theorems, basis reduction, gauge functions.
- Good order of magnitude if DS is a polyhedron.
Modular mappings and lattices

Modulo mapping \( \vec{i} \mapsto \sigma(\vec{i}) = M\vec{i} \mod \vec{b} \) (modulo componentwise).

Validity iff \( \vec{i} \not\parallel \vec{j}, \vec{i} \neq \vec{j} \Rightarrow \sigma(\vec{i}) \neq \sigma(\vec{j}) \) iff, with \( \text{DS} = \{\vec{i} - \vec{j} | \vec{i} \not\parallel \vec{j}\} \), \( \text{DS} \cap \ker \sigma = \{\vec{0}\} \).

Lattice An allocation is optimal iff its kernel is a strictly admissible (integer) lattice for DS of minimal determinant (critical lattice).

Critical Lattice: Basis \((4,3), (8,0)\) \(3\vec{i} - 4\vec{j} \mod 24\) Determinant: 24

- Successive modulo approach.
- Exhaustive search possible.
- Upper/lower bounds linked to Minkowski’s theorems, basis reduction, gauge functions.
- Good order of magnitude if DS is a polyhedron.
Dealing with union of polyhedra: new theory

Live-out set of a tiled code:

- Successive modulo:
  \[(x, y) \mapsto (x \mod N, y \mod N)\].

- Skewed mapping:
  \[(x, y) \mapsto (x - y \mod (2N - 1), y \mod 2)\].

How to find the second one?
Dealing with union of polyhedra: new theory

Live-out set of a tiled code:

- Successive modulo:
  \((x, y) \mapsto (x \mod N, y \mod N)\).

- Skewed mapping:
  \((x, y) \mapsto (x - y \mod (2N - 1), y \mod 2)\).

How to find the second one?
Many pieces of the puzzle get together

New generalizations and links with previous approaches.

- Liveness analysis for parallel specifications.
- Interference graph structure analysis and exploitation.
- Lattice-based memory allocation extensions.

Towards a better understanding of parallel languages: semantics, static analysis, and links with the runtime.

And to conclude on tiling:

- Many other extensions exist: tile shapes, parallelism, cost models, etc. See talks by Uday, Sven, Ram.
- Still a need for performance models to guide transformations, parametric tiling is one step. See talk by Markus on perf. models.
- Need to integrate user/algorithm freedom. Ex: domain decomposition to define parallel tiles, multipartitioning for ADI codes, etc.
